Abstract

_Acanthamoeba_ keratitis (AK) is a sight threatening infection caused by the free-living amoeba _Acanthamoeba_. This infection is largely associated with contact lens wear and the recent increase in AK incidences highlights the ineffectiveness of existing curative and preventative treatments. Current curative and protective treatments being active in part, only against the infective trophozoites and often inducing their conversion to the protective cysts is a major issue, particularly when the latter are the main cause of disease resurgences and relapses. These point to the need for the discovery of new drugs for curative and preventive treatments. Two structurally similar chemical classes, alkylphosphocholines (APCs) and quaternary ammonium compounds (QACs) that address these issues will be discussed in this review.

Introduction

_Acanthamoeba_ are free-living single celled eukaryotes, existing in two forms; an infective trophozoite and a dormant cyst. They are ubiquitously found in both natural and man-made environments and are of clinical relevance due to their opportunistic parasitic activities in humans1. There are several _Acanthamoeba_ associated infections in humans, but this review will focus on the sight threatening disease of the eye _Acanthamoeba_ keratitis (AK)2 and the use of two promising compounds as curative and preventive treatments that will validate its incorporation into contact lens solutions. Curative treatment is the use of systemic oral drugs and topical eye drops while preventive treatment employs medical devices e.g. contact lens solutions to sterilise contaminated lenses and prevent contact lens to eye transmission.

AK is largely associated with improper contact lens hygiene and the limited activity of contact lens solutions against _Acanthamoeba_. The attachment of _Acanthamoeba_ to contact lens allows transmission to, and infection of the cornea arising from the feeding activities of trophozoites in the eye3. Incidence rates of AK have been increasing globally since the start of the 21st century. On average, the annual number of AK cases within the Moorfields eye hospital, England increased from 12.8 to 48.6 between 2000-2008 and 2009-20164, and 16 to 49 in the Netherlands between 2009 and 20155. Similar reports are documented in Australia and the USA with rising incidences, the Sydney Eye Hospital reported the annual average cases of AK to be 2.6 and 3.6 before and after 20076, while cases in Iowa, USA increased in average annual cases from 2.9 to 6.5 between 2002-2009 and 2010-2017 respectively7. The reasons for this spatio-temporal increase are not readily apparent but improved diagnostic
techniques and ineffective contact lens cleansing solutions are thought to be key factors⁴.

Existing curative and preventive treatments for AK mainly target trophozoites but become inactive if they induce their conversion to cysts via the process of encystation⁸. The cellulose cell walls of cysts protect the parasite against drug activity⁹,¹⁰ and the reduction of drug concentrations in the eye to sub-lethal levels initiates the reversion of cysts to the trophozoite stage, ultimately leading to disease resurgence¹⁰.

The inability of current topical and oral drugs and many widely used contact lens solutions to produce death at low concentrations against cysts, the requirement of a prolonged treatment regime to ensure complete clearance from the eye and the ability to induce encystation are factors that have made AK treatment and prevention difficult¹¹. In some instances, frequent application of drugs topically for up to a year is required, causing corneal damage and very often patients require surgical intervention e.g. corneal transplant to repair the damaged cornea¹⁰,¹². Preventive protocols with commonly used contact lens solutions such as one-step hydrogen peroxide solutions are similarly ineffective with even compliant users at risk¹³,¹⁴.

Two structurally similar compounds named alkylphosphocholines (APCs) and quaternary ammonium compounds (QACs) have received attention for their activity against several protozoan pathogens, including Acanthamoeba¹⁵–²⁰. These compounds are active against cysts and synergistic with other antimicrobials including Acanthamoeba spp¹⁵–²¹. Work by Walochnik and colleagues on their anti-amoebic properties for combating Acanthamoeba keratitis concluded that APCs are promising drug candidates that might prove useful against AK²¹. This minireview provides an update and the state of the art of this chemical class and an analogue called QACs, extensively used as preventative strategy against AK.

Alkylphosphocholines against Acanthamoeba Keratitis

Structure of alkylphosphocholines

APCs are zwitterionic molecules comprised of a head made from a trimethylamine moiety containing a positively charged nitrogen atom and joined by a two alkyl-carbon linker to a negatively charged phosphoryl group. The tail, made of varied number of alkyl-carbons, is attached to the phosphoryl group (Figure 1).

### Activity of oral miltefosine against Acanthamoeba keratitis

The APC, miltefosine was first developed as an anti-cancer drug but was subsequently shown to have anti-fungal and anti-protozoal properties²²,²²–²⁷. Systemic use of miltefosine was licensed in the USA as a treatment of AK in 2016 and when incorporated into treatment regimens at 50mg/ml, given three times daily (TD) for up to two months has proved to be an effective oral systemic treatment against Acanthamoeba mainly in combination¹⁵,²⁸ (Table 1). The use of miltefosine solely as an oral administration is yet to be tested, but in combination with topical applications e.g. chlorhexidine (0.06%) and propamidine (0.1%) has demonstrated success¹⁵. Hirabayashi et al.¹⁵ reported the use of miltefosine in the treatment of a patient suffering with progressively worsening AK. For this 17yr old female patient, earlier treatments with topical polyhexamethylene biguanide (PHMB, 0.02%), chlorhexidine (0.02%), moxifloxacin (0.5%), cyclopentolate (1%) and oral administration of both 500mg valacyclovir and 200mg voriconazole twice daily (BD) were unsuccessful. The addition of miltefosine (50mg, TD, orally) in particularly with topical chlorhexidine (0.06%) and propamidine isethionate (0.1%) for five weeks reduced the infection and accompanying symptoms, pain improved conjunctival injection and corneal opacity were reduced and improved respectively¹⁵. No resurgence was observed one-year post treatment¹⁵ (Table 1). Similar results have been described by Dewan et al.²⁸, again a 44yr old female who did not respond to treatment with topical chlorhexidine (0.02%), PHMB (0.02%), gatifloxacin (0.3%) and voriconazole (0.5mg/ml) and oral voriconazole (200mg, BD) was responsive to oral miltefosine (50mg, TD) after 11 months of treatment²⁸ (Table 1). Resurgence was not evident thirty-month post treatment²⁸. The efficacy of miltefosine is reproducible and has been replicated in part by Naranjo et

Activity of topical miltefosine against Acanthamoeba keratitis

The success of oral miltefosine suggests that it can be absorbed easily by the gut, is able to survive the first pass effect in the liver and the bioavailability in the eye is of sufficient concentration to cause Acanthamoeba death. This suggests that lower doses would be sufficient for topical use. Work done by Polat et al. demonstrated that the topical application of miltefosine alone to the Acanthamoeba-infected eyes of Syrian hamsters for 28 days at 160μM cleared AK infections by 85% (Table 2). In contrast, the current recommended topical treatment combinations of 0.1% propamidine isetionate and 0.02% PHMB was less effective in the eyes of Syrian hamsters than miltefosine alone. The same group reported further benefits for the use of miltefosine as a combined topical treatment against Acanthamoeba keratitis in rats. Miltefosine (160μM) combined with PHMB (0.02%) or chlorhexidine (0.02%) but not propamidine isethionate (0.1%) showed synergistic activity (Table 2). This study illustrated that existing topical treatments with PHMB can be improved by the addition of topical miltefosine. We thus propose that miltefosine should be integrated with current treatment regimens for improved prognosis for patients.

In vitro activity of APCs against Acanthamoeba

There are several in vitro studies describing the efficacy of APC analogues against Acanthamoeba with most showing miltefosine (hexadecylphosphocholine) to have optimal activity against Acanthamoeba trophozoites (Table 3). In a structure activity relationship study undertaken by Mooney and colleagues, a series of APCs with different alkyl-carbon chain length ranging from 8-18 carbons, demonstrated that miltefosine was cytotoxic at 46μM and cytostatic below this dosage against trophozoites. Another study showed that 39mM to 78mM of miltefosine was toxic to cysts. Similar results reported elsewhere for miltefosine have shown that the activity of miltefosine against Acanthamoeba is influenced by the length form, the Acanthamoeba species, the strain, and the duration of the drug in contact with the protist. Nevertheless, they have shown that approximately 3000-fold lower concentrations of miltefosine was required for in vitro treatment than for topical and oral application (Table 3). This makes a good case for their incorporation into contact lens solutions as a preventive strategy. Studies show that human tissues such as the eye, organotypic skin models and mammalian breast cancer cells are refractory to miltefosine concentrations 160μM, 50μM and 150mM respectively which suggest that it could be safe to use as a preventive strategy and eye toxicity would not be an issue.

Quaternary Ammonium Compounds Against Acanthamoeba

Structure and classification of quaternary ammonium compounds

QACs lack the negatively charged phosphoryl group of APCs resulting in a net positive charge. They are cationic molecules containing a positively charged central nitrogen atom attached to four substituents. Attachments to aliphatic and aromatic functional groups have produced two main types of QACs. In this review, they will be referred to as benzylated and non-benzylated if the compound contains an aromatic benzyl ring (e.g. benzalkonium chloride and benzethonium chloride) or lacks one (e.g. tetraethylammonium bromide and dodecyltrimethylammonium bromide) attached to the nitrogen atom respectively (Figure 2).

| AK eye model         | Miltefosine prepared at 2mM dissolved in 5% ethanol | Group 1 - Miltefosine (160μM)  
Group 2 - Propamidine isethionate (0.1%) and PHMB (0.02%) combination | Group 1 – 85% of eyes were normal with cultures of excised post-treatment tissues negative for Acanthamoeba  
Group 2 – 65% of eyes were normal with 5% cultures of excised post-infection tissues positive for Acanthamoeba.  
Infected Control group – 5% of eyes were normal with 6% of culture of excised tissues positive for Acanthamoeba.  
Conclusion: Topical miltefosine was more effective in treating AK than propamidine isethionate and PHMB combinations often used in treating AK. |
| AK eye model         | 2mM of Miltefosine prepared at 2mM in 5% ethanol | Group 1 - Miltefosine (160μM)  
Group 2 – chlorhexidine gluconate (0.02%)  
Group 3 – PHMB (0.02%)  
Group 4 – propamidine isethionate (0.1%)  
Group 5 – Miltefosine (160μM) and chlorhexidine gluconate (0.02%) combination  
Group 6 – Miltefosine (160μM) and PHMB (0.02%) combination  
Group 7 – Miltefosine (160μM) and propamidine isethionate (0.1%) combination  
Infected Control group - Ethanol in PBS (0.05%) | Group 1 – 14.2% and 50% of eyes were normal or almost normal respectively with 28.5% cultures of excised tissues positive for Acanthamoeba.  
Group 2 – 7.1% and 50% of eyes were normal or almost normal respectively with 28.5% of cultures of excised tissues positive for Acanthamoeba.  
Group 3 – 7.1% and 42.8% of eyes were normal or almost normal respectively with 21.4% cultures of excised tissues positive for Acanthamoeba.  
Group 4 – 7.1% and 35.5% of eyes were normal or almost normal with 28.5% cultures of excised tissue positive for Acanthamoeba.  
Group 5 – 14.2% and 57.1% of eyes were normal or almost normal respectively with 21.4% cultures of excised tissues positive for Acanthamoeba.  
Group 6 – 28.4% and 64.2% of eyes were normal or almost normal respectively with 14.2% cultures of excised tissue positive for Acanthamoeba.  
Group 7 – 7.1% and 35.5% of eyes were normal or almost normal respectively with 21.4% of cultures of excised tissues positive for Acanthamoeba.  
Infected Control group - 0% and 21.4% of eyes were normal or almost normal respectively with 71.4% cultures of excised tissues positive for Acanthamoeba.  
Conclusion: Topical treatments of miltefosine combined with PHMB or chlorhexidine were synergistic; while combinations with propamidine isethionate were additive. PHMB-miltefosine combination is an effective treatment for AK. |

<td>Polyquad-1</td>
<td>Cysts of <em>A. castellanii</em>, <em>A. polyphaga</em>, <em>A. hatchetti</em> treated with 0.001% Polyquad-1 formulated in the contact lens solutions Alcon Opti-Clean II, Alcon Opti-Free Express, Alcon Opti-Free Replenish for 24 hours</td>
<td><strong>Findings:</strong> Viable cysts were observed for all 3 <em>Acanthamoeba</em> spp. after 24 hours incubation in all Polyquad-1–contact lens solution formulations <strong>Conclusion:</strong> Polyquad-1 concentrations in contact lens solutions are inactive against <em>Acanthamoeba</em> cysts</td>

<td>nbQAC</td>
<td>Benzalkonium chloride (BAC)</td>
<td>Trophozoites and cysts of <em>A. castellanii</em>, <em>A. polyphaga</em> treated with BAC at concentrations ranging from 2.7-134μM (0.005-0.02%) for 48 hours in the BAC containing solutions Levofloxacin (Oftaquix; 0.005% BAC), trifluorothymidine ( 0.02% BAC)</td>
<td><strong>Findings:</strong> BAC monotherapy was effective in killing trophozoites at concentrations of 0.02μM and 0.005μM and cysts at concentrations of 0.04μM and 0.02μM for <em>A. castellanii</em> and <em>A. polyphaga</em> respectively. The Levofloxacin (Oftaquix) ophthalmic solution with 0.005% BAC has a minimal amoebicidal concentration of 156μg/ml and 312μg/ml and cysticidal concentration of 625μg/ml and 625μg/ml for <em>A. castellanii</em> and <em>A. polyphaga</em> respectively. For TMT containing 0.02% BAC these same respective concentrations were 625μg/ml and 1250μg/ml for trophozoites and 5000μg/ml and 2500μg/ml for cysts. <strong>Conclusion:</strong> BAC is highly potent to <em>Acanthamoeba</em> trophozoites and cysts and addition to contact lens solutions significantly increases efficacy.</td>

solutions as topical and preventive strategies, and can cause death at concentrations ranging from 2.69μM to 20.97M and 20.97μM to 41.93μM against trophozoites and cysts respectively, far lower than that in ophthalmic solutions as topical and preventive strategies, and can cause eye irritation at concentrations above 510mM, while ~1200-fold (42μM) lower doses are required for activity against Acanthamoeba. For example, octadecyldimethylammonium bromide causes severe eye irritation at concentrations above 510mM, while ~1200-fold (42μM) lower doses are required for activity against Acanthamoeba. Nevertheless, studies are required to validate QACs as a preventative strategy. Should corneal toxicity be an issue, neutralising agents such as β-cyclodextrin could provide a second step during contact lens cleansing. Two-step methods have been effectively used for hydrogen peroxide based contact lens solutions.

**Conclusion**

The impact of APCs in AK treatments, even amongst the ‘difficult to treat’ immuno-suppressed patients is promising. Despite the clinically observed effect, little
is known about its clinical pharmacodynamics, mainly because good quantitative markers of parasite load and treatment response are not available for AK. Disease-specific pharmacokinetics for miltefosine alone and in combination are available for other anti-parasitic infections e.g. Leishmaniasis but are yet to be available for AK. Further clinical research is required for these compounds to be used as a treatment or preventative. Similarly, pharmacodynamics and pharmacokinetic studies of QACs are scarce and are perhaps hampered by their extensive use as preservatives. The strong efficacy of QACs against Acanthamoeba is a framework for development as a treatment or preventative for AK, if corneal toxicity issues are addressed.
